(57) **ABSTRACT**

An actuator for actuating a plunger of a valve is provided. The actuator has an inlet and includes first and second hollow caps. A main actuation assembly is provided between the caps. The main actuation assembly includes a deformable diaphragm; first and second chambers, static sealing elements and a main piston movable between actuated and unactuated positions. A biasing mechanism biases the piston in the unactuated position. When pressurized gas is flown through the inlet and/or drawn from the outlet of the actuator, the first chamber expands, moving the main piston from the unactuated position to the actuated position, an actuating stem connected to the main piston thereby sliding within a channel provided in the bottom cap. Stackable actuating assemblies can also be used between the caps. Using static sealing elements advantageously avoids friction between moving parts.

CROSS-REFERENCE TO RELATED APPLICATIONS

The present application is a continuation-in-part of U.S. Ser. No. 14/487,374, filed Sep. 16, 2014, which is a continuation of U.S. patent application Ser. No. 13/542,244, filed Jul. 5, 2012, which claims the priority benefit of U.S. Provisional Patent Application Ser. No. 61/508,095, filed Jul. 15, 2011, each of which is incorporated by reference in its entirety herein.

FIELD OF THE INVENTION

The present invention generally relates to actuators and more particularly concerns a pneumatic actuator used to actuate plungers or pistons in valves.

BACKGROUND

Pneumatic actuators are used in different types of applications, and serve to actuate or move plungers, shafts and the likes in different types of devices, such as valves.

An actuator can include a normally closed piston, a normally open piston, or both within the same assembly. An actuator including a normally closed piston is typically provided with a biasing element, such as a spring or Belleville washers, which biases the piston in a closed position. In order to move the piston from the closed to the open position, gas is injected within the actuator, counteracting the biasing action of the spring and allowing the piston to move towards the open position. Similarly, normally opened pistons may be biased in their open position and moved to the closed position through the effect of gas pressure thereon.

In order to isolate and seal the chamber in which the gas is injected, dynamic seals are generally used. An example of valve construction based on this principle is shown in FIG. 1 (PRIOR ART). In this example, the normally closed and normally open pistons 12, 14 of an actuating mechanism 10 are both provided with polymer, silicone or rubber O-rings 16 along their outer periphery. When the pistons move up and down within the valve, the O-rings 16 slide and rub against the inner wall of the cylindrical body 18 of the valve.

When actuators are used in high-temperature applications, sometimes as high as 350° C., the dynamic seals tend to become sticky and brittle over time. This increases the friction between the seal and the inner wall of the actuating system, impairing movement of the pistons. Lubricants can be used to minimize this friction, but their use generates other problems: grease-based lubricants, such as Krytox (trademark) or Torr-lube (trademark) eventually dry down, increasing even more the friction and making it harder for the pistons to move. The use of dry lubricants is usually not considered an alternative, as they are eventually blown away by the actuating gas used. Similar difficulties are also encountered in solenoid valves in which the pistons are actuated using an electrical current.

The degradation of the dynamic seals does not only occur in high temperature applications. The problem is also present in cryogenic applications, where valves are used in very low temperature conditions. In this case, the humidity present in the actuating gas tends to crystallize at the interface of the pistons and the inner wall of the actuating system, impairing the movement of the pistons.

2

There is thus a need for an actuator which can help reduce or eliminate friction between moving parts. For some applications, it would also be desirable for this actuator to impart a higher force to the shaft or plunger it actuates, while keeping the actuating pressure low. For some applications, the mechanism would also need to have a long operating life and be able to move the shaft or plunger at high speed.

Many solutions have been proposed in order to solve this issue. U.S. Pat. No. 5,755,428 shows a valve having a metal-to-metal dynamic seating. While the described type of actuator may be appropriate for ambient or relatively medium temperature, it is not readily usable in high temperature or cryogenic applications. There are 6 O-rings involved in this design. High friction and embrittlement of those O-rings is likely to result if used at cryogenic or at high temperature, like 350° C.

Also known in the art are U.S. Pat. No. 5,131,627, U.S. Pat. No. 5,215,286, U.S. Pat. No. 5,653,419, U.S. Pat. No. 6,508,453, U.S. Pat. No. 7,159,839 and US 20100090151. Some of these solutions use cam mechanisms, gear-cam and pinion mechanisms, or multiple pistons in order to increase the effective total weight or force to the actuated shaft or rod. These solutions require the use of several small hard-to-machine parts which render the mechanism complex and difficult to assemble or maintain, in addition to increasing the manufacturing costs.

In light of the above, there is a need for an improved pneumatic actuator.

SUMMARY OF THE INVENTION

In accordance with an aspect of the present invention, there is provided a pneumatic actuator for actuating a plunger. The actuator can be used in different applications, such as, but not limited to, analytical, process, instrumentation or industrial applications. It can be also used from cryogenic to high temperature applications.

The actuator comprises a main inlet and a main outlet, and first and second hollow caps facing one another. The second cap is provided with a cap channel extending therethrough.

The actuator also comprises a main actuation assembly provided between the first and second hollow caps. This main actuation assembly includes a deformable diaphragm having opposite first and second diaphragm surfaces, a first chamber and a second chamber. The first chamber is limited by the first diaphragm surface and is in fluid communication with the main inlet. The second chamber is limited by the second diaphragm surface, and is in fluid communication with the main outlet.

The actuator also comprises static sealing elements for fluidly sealing the first and second chambers.

The actuator also comprises a main piston and an actuating stem. The main piston is movable between actuated and unactuated positions, and includes a piston surface operatively attachable to the second diaphragm surface. The actuating stem slidably fits in the cap channel, a portion of the stem extending outside of the second cap, said portion of the stem being connectable to the plunger. The actuating stem cooperates with the main piston so as to slide within the cap channel when the main piston moves between the actuated and unactuated positions.

The actuator also comprises a biasing mechanism biasing the piston in the unactuated position.

When pressurized fluid is forced through the main inlet or drawn from the main outlet, or both, the first chamber of the main actuating assembly expands, moving the main piston

from the unactuated position to the actuated position, the actuating stem thereby sliding within the cap channel

By flexible diaphragm, it is meant a flexible membrane or component adapted to deform.

Advantageously, the use of a deformable diaphragm in the actuating mechanism of the present invention eliminates the need for dynamic seals, that is, seals which move with the pistons in conventional actuating mechanisms. Avoiding the use of conventional seals reduces friction of parts within the actuator, increasing in turn the lifetime of the actuating mechanism, regardless of temperature conditions in which it is used. In order to preserve the air-tight properties of the chambers within the mechanism, static seals can be used, such as copper gaskets.

Preferably, the actuator can also comprise at least one stackable secondary actuating assembly disposed between the first and second caps. Each assembly comprises a cartridge inlet and a cartridge outlet. Each assembly also comprises an actuating cartridge, an intermediate deformable diaphragm, first and second intermediate chambers, static cartridge sealing elements, and an intermediate piston. The actuating cartridge is provided with a cartridge channel. The intermediate deformable diaphragm has opposite first and second surfaces. The first intermediate chamber is limited by the first surface of the intermediate diaphragm, and is in fluid communication with the cartridge inlet. The second intermediate chamber is limited by the second surface of the intermediate diaphragm, and is in fluid communication with the cartridge outlet.

The static cartridge sealing elements are for fluidly sealing the first and second intermediate chambers. The intermediate piston is movable between the actuated and unactuated positions and includes a piston surface operatively attached to the second surface of the intermediate diaphragm. The intermediate piston slidably fits in the cartridge channel and operatively cooperates with the main piston.

When pressurized fluid is forced through the cartridge inlet or drawn from the cartridge outlet, or both, the first intermediate chamber expands, moving the intermediate piston from the unactuated position to the actuated position, assisting the sliding of the actuating stem within the cap channel.

Advantageously, the use of one or several stackable secondary actuating assembly(ies) allows increasing the force applied on the actuating stem.

In addition, the use of stackable actuating and/or biasing element cartridges allows modifying and controlling the torque and weight force applied on the actuating shaft, allowing easy customization of the actuating mechanism depending on the requirements of the applications for which it is to be used.

In one embodiment, the actuator comprises one or several stackable biasing element cartridges, connected to one of the first and second caps.

In one embodiment, the actuator is a normally open actuator, the second cap is provided with a circular recess, the biasing mechanism fitting in said circular recess. The main outlet is a vent provided in the second cap and the first chamber is limited by the first cap.

In one embodiment, the actuator is a normally closed actuator, the first cap being provided with a circular recess, the biasing mechanism fitting in the circular recess. The main outlet is a vent provided in the first cap and the first chamber is limited by the second cap.

In one embodiment, the static sealing elements are either brazed joints, polymeric gaskets and metal gaskets, or a combination thereof.

In one embodiment, the cartridge inlet(s) of the at least one stackable secondary actuating assembly(ies) are in fluid communication with the main inlet.

In one embodiment, the actuator comprises a second actuating stem, for actuating a second plunger. The first cap is provided with a second cap channel extending there-through, the second actuating stem slidably fitting in the second cap channel. A portion of the second actuating stem extends outside of the second cap and is connectable to the second plunger. The second actuating stem slides within the cap channel when the main piston moves between the actuated and unactuated positions. For each stackable actuating assembly, the cartridge inlet is in fluid communication with the main inlet. When pressurized fluid is forced through the cartridge inlet and/or drawn from the cartridge outlet, the first chamber(s) expand(s), the second actuating stem moving with the main piston from the unactuated to the actuated position, both actuating stems thereby moving within their respective cap channels. As such, the first and second actuating stems can move in the same direction, or in opposite directions.

In one embodiment, the actuator is used in combination with a current to pressure converter.

According to another aspect of the invention, there is also provided a kit for mounting an actuator as defined above. The kit comprises the first and second hollow caps, the main actuation assembly including the deformable diaphragm, the main piston, and the static sealing elements, the actuating stem connectable to the main piston; and the biasing mechanism for biasing the piston in the unactuated position.

According to yet another aspect of the invention there is also provided a stackable secondary actuating assembly for use in an actuator as defined above. The stackable secondary actuating is for use between the first and second caps and comprises an actuating cartridge, first and second intermediate deformable diaphragms, an intermediate piston, and static cartridge sealing elements for fluidly sealing the first and second intermediate deformable diaphragm with other components of the valve, when in use.

Other features and advantages of the present invention will be better understood upon reading of preferred embodiments thereof, with reference to the appended drawings.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 (PRIOR ART) is a cross-sectional view of a valve including a prior art actuator, including dynamic seals.

FIG. 2 is a top perspective view of an actuator, according to a first preferred embodiment of the invention. FIG. 2A is an exploded view of the actuator shown in FIG. 2. FIG. 2B is a cross-sectional view of the actuator of FIG. 2, taken along line B-B. FIG. 2C is a cross-sectional view of the actuator of FIG. 2, taken along line B-B, showing the flow of pressurized fluid within the actuator.

FIG. 3 is a top perspective view of an actuator, according to a second preferred embodiment of the invention. FIG. 3A is an exploded view of the actuator shown in FIG. 3. FIG. 3B is a cross-sectional view of the actuator of FIG. 3, taken along line B-B. FIG. 3C is a cross-sectional view of the actuator of FIG. 3, taken along line B-B, showing the flow of pressurized fluid within the actuator.

FIG. 4 is top perspective view of an actuator, according to a third preferred embodiment of the invention.

FIGS. 5A and 5B form an exploded view of the actuator of FIG. 4.

FIG. 6 is a cross-sectional view of the actuator of FIG. 4.

5

FIGS. 7 and 8 are top and bottom cross-sectional perspective views of the actuator of FIG. 4.

FIG. 9 is a cross-sectional perspective view of some of the components of a stackable secondary actuating assembly of the actuator of FIG. 4.

FIG. 10 is a cross-sectional exploded view of FIG. 9.

FIG. 11 is a cross-sectional view of the actuator of FIG. 4, showing the flow of pressurized fluid within the actuator.

FIG. 12 is top perspective view of an actuator, according to a fourth preferred embodiment of the invention.

FIGS. 13A and 13B form an exploded view of the actuator of FIG. 12.

FIG. 14 is a cross-sectional view of the actuator of FIG. 12.

FIGS. 15 and 16 are top and bottom cross-sectional perspective views of the actuator of FIG. 12.

FIG. 17 is a cross-sectional perspective view of some of the components of a stackable secondary actuating assembly of the actuator of FIG. 12.

FIG. 18 is a cross-sectional exploded view of FIG. 17.

FIG. 19 is a cross-sectional view of the actuator of FIG. 12, showing the flow of pressurized fluid within the actuator.

FIG. 20 is a cross-sectional view of an actuator, according to a fifth preferred embodiment of the invention.

FIG. 21 is a cross-sectional perspective view of some of the components of a stackable secondary actuating assembly of the actuator of FIG. 20.

FIG. 22 is an exploded view of FIG. 21.

FIG. 23 is a top perspective view of an actuator, according to a sixth preferred embodiment of the invention. FIG. 23A is an exploded view of the actuator shown in FIG. 23. FIG. 23B is a cross-sectional view of the actuator of FIG. 23, taken along line B-B, showing the flow of pressurized fluid within the actuator.

FIG. 24 is a top perspective view of an actuator, according to a seventh preferred embodiment of the invention. FIG. 24A is a cross-sectional view of the actuator of FIG. 24, taken along line A-A, showing the flow of fluid within the actuator. FIG. 24B is a cross-sectional view of the actuator of FIG. 24, taken along line B-B, showing the flow of pressurized fluid within the actuator.

FIG. 25 is a schematic view of an actuator according to preferred embodiment of the invention, in combination with a current to pressure converter.

FIG. 26 is a cross-section view of an actuator according to another embodiment of the invention.

FIG. 27 is a cross-section view of an actuator according to another possible embodiment.

FIG. 28 is a cross-section view of an actuator according to yet another possible embodiment.

While the invention will be described in conjunction with example embodiments, it will be understood that it is not intended to limit the scope of the invention to such embodiments. On the contrary, it is intended to cover all alternatives, modifications and equivalents as may be included as defined by the present application.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS OF THE INVENTION

In the following description, similar features in the drawings have been given similar reference numerals. To preserve the clarity of the drawings, some reference numerals have been omitted, if they were already identified in a preceding figure.

The embodiments described below are given by way of example only and the various characteristics and particu-

6

larities thereof should not be considered limitative to the scope of the present invention. It will be appreciated that positional descriptions such as "top", "bottom" and the like should, unless otherwise indicated, be taken in the context of the figures and should not be considered limiting.

With reference to FIG. 2, an actuator 20_{nc} for actuating the plunger of valve is shown. The actuator 20_{nc} includes a first cap 22_{nc} and a second cap 24_{nc}, a main inlet 28 and a main outlet 30. The inlet 28 and outlet 30 are ports through which fluid can be forced or drawn. The main inlet 28 is provided in the top cap 22_{nc}. The first and second caps are respectively top and bottom caps 22_{nc}, 24_{nc} and they are facing one another. The top and bottom caps 22_{nc}, 24_{nc} are preferably hollow, and by hollow it is meant that they have at least one recessed portion, even if only slightly recessed. The top and bottom caps 22_{nc}, 24_{nc} shown are cylindrical; however other configurations can be considered.

With reference to FIGS. 2A, 2B and 2C, the actuator 20_{nc} includes the main inlet 28, the top and bottom caps 22_{nc}, 24_{nc}, a main actuating assembly 25_{nc}, an actuating stem 42, and a biasing mechanism 32. The main inlet 28 is for receiving pressurized fluid, and while in this embodiment, the inlet 28 is provided in the top cap 22_{nc}, as a channel extending axially within the cap 22_{nc}, it can be considered to locate the inlet elsewhere, such as on the sidewall of the bottom cap 24_{nc} for example. The pressurized fluid can be of any type, gas or liquid.

The actuator 20_{nc} includes a main actuation assembly 25_{nc}, provided between the top and bottom hollow caps 22_{nc}, 24_{nc}. The main actuation 25_{nc} assembly includes a deformable diaphragm 36, a first chamber 48_{nc}, a second chamber 50_{nc}, a main piston 34_{nc} and static sealing elements 38a, 38b, 38c, 38d. In the present case, the static sealing elements are metallic gaskets; however, other types of static sealing elements can be considered, such as polymeric gaskets but also brazed joints. By static sealing elements, it is meant that the sealing elements do not move when the actuator is actuated, and thus there is no friction between the sealing elements or joints and the other components of the actuator. Sealing elements 38a, 38b, 38c and 38d are used to ensure that the first and second chambers 48_{nc}, 50_{nc} are properly sealed, and that the connections between the components are fluid tight.

The deformable diaphragm 36 is circular, with two opposite first and second surfaces 360, 362 and a central hole 364. It is flexible enough to deform under the pressure of a fluid or when being pushed or pressed, and is preferably corrugated. The flexible diaphragm can be any type of fluid tight membrane or component able to move or deform. A flexible diaphragm can be made from different types of materials, such as metals, polymers and/or elastomers. A combination of such elements can also be used. It can also be considered to use bellow(s) as flexible diaphragm(s). Bellows, which are typically made of metal, are elastic vessels that can be compressed when pressure is applied to the outside of the vessel, or extended under vacuum.

The first chamber 48_{nc} is limited by the first diaphragm surface 360 and is in fluid communication with inlet 28, as best shown in FIG. 2C. The first chamber 48_{nc} is airtight in the sense that it can inflate when the actuator 20_{nc} is in use, that is, when connected to a source of pressurized fluid. The second chamber 50_{nc} is limited by the second diaphragm surface 362 and is in fluid communication with the main outlet 30, for expelling fluid. In the present case, the main outlet 30 is a vent.

The main piston 34_{nc} has a piston surface operatively attached to the second surface 362 of the diaphragm 36. In

7

the present case, the piston surface is part of a flange 340, extending in the second chamber 50nc. The main piston can move between actuated and unactuated positions. The actuator of FIGS. 2A-2C is a normally closed actuator: when it is unactuated, that is, when no pressurized fluid is injected through the inlet 28, the biasing mechanism 32, which is in this case an helicoidal spring, presses flange 340, maintaining piston 34nc in a lowered position. When in the actuated position, pressurized fluid is filling the first chamber 48nc, and the first chamber expands, deforming the diaphragm 36, thereby pushing flange 340 upwardly, which in turn compresses the biasing element 32, the piston being in a raised position, as best shown in FIG. 2C. The flange section 340 has a first surface in contact with the biasing element 32, and a second surface with the second diaphragm surface 362. The arrows in FIG. 2C show the flow of pressurized fluid entering trough inlet 28 and filling the first chamber 48nc.

Still referring to FIGS. 2A-2C, the main piston 34nc is provided with a portion 342 passing through the central hole 364 of the diaphragm, extending in the first chamber 48nc. A diaphragm retaining nut 60 is screwed on the portion 342, the central portion of the diaphragm being sealingly compressed between the nut 60 and the flange 340 of the main piston 34nc. A first circular gasket 38c is used for ensure airtight connection of the nut 60, of the region around the central hole 364 of the diaphragm 36 and of the main piston 34nc. Similarly, the outer periphery of the diaphragm 36 is sealingly compressed, between the top and bottom caps 22nc, 24nc, and second circular gasket 38b is used to seal the connection. Of course, other sealing and connecting elements can be considered as long as the first chamber 48nc is airtight when pressurized fluid is injected in the chamber 48nc. The top and bottom caps 22nc, 24nc are provided with threads on their respective lateral walls, and are connected together by screwing. Of course, it can also be considered to join them by soldering or brazing.

An actuating stem 42, or shaft, is sized and shaped to fit in a channel 240, provided in the bottom cap, also referred to as cap channel 240. The actuating stem can slide within the cap channel 240. A portion of the stem 42 extends outside of the bottom cap 24nc. This portion of the stem 42 extending outside the bottom cap 24nc can be connected to a plunger of a valve, or to any other type of device requiring a linear motion. The other side of the stem 42 is operatively connected to the main piston 34nc, so as to slide within the cap channel 240 when the main piston 34nc moves between the actuated and unactuated position. By operatively connected, it is meant that they can be directly or indirectly connected to one another. They can also be integral with one another, that is, part on the same component. In the present case, the stem 42 is connected, or linked, to the main piston 34 via the screw 57, the main piston resting on the head of the screw 57.

The biasing mechanism 32, in this case a helicoidal spring, biases the piston 34nc in the unactuated position. The biasing element 32 fits in a circular recess 220 provided in the top cap 22nc. As best shown in FIG. 2C, when pressurized fluid is flow through the inlet 28, the first chamber 48nc of the main actuating assembly 25nc expands, moving the piston from the unactuated to the actuated position. The biasing element 32 is thus compressed, allowing the actuating stem 42 to slide within the cap channel 240.

The first chamber 48nc is limited by the bottom cap 24nc. When the first chamber 48nc expands, the second chamber 50nc deflates, since the two chambers are contained in a fixed enclosure formed by the top and bottom caps 22nc, 24nc. The air or fluid contained in the second chamber 50nc

8

is expelled via the vent 30, which is provided in the top cap 22nc. In order to allow the actuating stem 42 to move while keeping the first chamber 48nc airtight, a second deformable diaphragm 52b delimits the first chamber 48nc. The second deformable diaphragm 52b is sealingly retained around its central hole by the screw 57 and the stem 42, and around its outer periphery between a flange of the bottom cap 24nc and a connecting/closing nut 64. The closing nut 64 can be screwed to the bottom cap 24nc, or fixed to it with a set screw. Similarly, another smaller diaphragm 52a allows movement of the piston 34nc while sealingly connecting the main piston 34nc to the top cap 22nc.

With reference to FIG. 3, another embodiment of an actuator according to the invention is shown. The actuator 20no includes a top cap 22no and a bottom cap 24no, and an inlet 28 is provided in the top cap 22no. This version of the actuator is a normally open actuator 20no.

With reference to FIGS. 3A, 3B and 3C, the actuator 20no includes a main inlet 28, first and second caps 22no, 24no, a main actuating assembly 25no, an actuating stem 42, and a biasing mechanism 33. The inlet 28 for receiving pressurized fluid is provided in the top cap 22no; however, it can be considered to locate the inlet 28 elsewhere.

The actuator 20no includes a main actuation assembly 25no, provided between the top and bottom hollow caps 22no, 24no. The main actuation 25no assembly includes a deformable diaphragm 36, a first chamber 48no, a second chamber 50no, a main piston 34no and static sealing elements 38b 38c.

The first chamber 48no is limited by the first diaphragm surface 360 and is in fluid communication with the main inlet 28. In this version of the actuator, the first chamber is on the top side of the diaphragm, rather than on the bottom side, as in the normally closed actuator of FIG. 2. Still referring to FIGS. 3A-3C, the second chamber 50no is limited by the second diaphragm surface 362 and is in fluid communication with the main outlet 30, which is in this case a vent for expelling gas. Static sealing elements 38c and 38d are used to ensure that the connections between the components of the actuator 20no are sealed and airtight, and they advantageously do not move when the piston 34no moves from the actuated to the unactuated positions.

The main piston 34no has a piston surface connectable to the second surface of the diaphragm 362. In this case, the piston surface is part of a flange section 340 extending in the second chamber 50no, underneath the diaphragm 36. The main piston 34no can move between actuated and unactuated positions. The actuator of FIGS. 3A-3C is a normally open actuator: when it is unactuated, that is, when no pressurized fluid is injected through the main inlet 28, the biasing mechanism 33 presses flange 340 and maintaining piston 34no in a raised position. When in the actuated position, pressurized fluid is filling the first chamber 48no, deforming the diaphragm 36, thereby pushing flange 340 downwardly, which in turn compresses the biasing element 33, the actuating stem 42 being in a lowered position, as best shown in FIG. 3C. The flange section 340 has a first surface in contact with the biasing element 33, and a second surface in contact with the second diaphragm surface 362. The arrows in FIG. 3C show the flow of pressurized fluid entering trough inlet 28 and filling the first chamber 48no.

Still referring to FIGS. 3A-3C, the main piston 34no is provided with a portion 342 passing through the central hole 364 of the diaphragm 36, extending in the first chamber 48no. The diaphragm retaining nut 60 is screwed on the portion 342, the diaphragm being sealingly compressed between the nut 60 and the flange 340 of the main piston

34no, around its central hole 364. The gasket 38c is used to provide a fluidtight connection between nut 60 and flange 340. Similarly, the outer periphery of the diaphragm 36 is sealingly compressed, between the top and bottom caps 22no, 24no, and gasket 38d is used to seal the connection. Of course, other sealing and connecting elements can be considered as long as the first chamber 48no is airtight when pressurized fluid is injected in the chamber 48no.

The actuating stem 42, or shaft, is sized and shaped to fit in the cap channel 240, provided in the bottom cap 24no. In this variant of the actuator, the stem 42 extends from the main piston 34no. The actuating stem 42 can slide within the cap channel 240. A portion of the stem 42 extends outside of the bottom cap 24no. By extending outside of the bottom cap, it is meant that it goes beyond the bottom wall of the cap 24no, outside of the lowermost chamber. Similar to the normally closed actuator 20nc, the portion of the stem 42 extending outside the bottom cap 24no can be connected to a plunger of a valve, or to any other type of device requiring a linear motion. The other side of the stem 42 is directly connected to the main piston 34no, as it extends from it and is integrally part of the main piston 34no.

The biasing mechanism 33, in this case a wave spring, biases the piston 34no in the unactuated position. The biasing element 33 fits in a circular recess 242 provided in the bottom cap 24no. Of course, other type of biasing elements can be used. As best shown in FIG. 3C, when pressurized fluid is flown through the inlet 28, the first chamber 48no of the main actuating assembly 25no expands, moving the piston 34no from the unactuated to the actuated position. The biasing element 33 is thus compressed, allowing the actuating stem 42 to slide within the cap channel 240.

The first chamber 48no is limited by the top cap 22no. When the first chamber 48no expands, the second chamber 50no deflates, since the two chambers are contained in the fixed enclosure formed by the top and bottom caps 22no, 24no, which as screwed to one another, with threads 222, 244. The air or fluid contained in the second chamber 50no is expelled via the vent 30, provided in the bottom cap 24no.

With reference to FIG. 4, an actuator 200nc according to another embodiment of the invention, is shown. This variant of the actuator is a normally closed actuator, and includes the first cap 22nc, two actuating cartridges 26nc, and the second cap 24nc. On the lateral wall of the top cap 22nc and the actuating cartridges 26 are cartridge outlets 31.

With references to FIGS. 5A, 5B and 6, the actuator 200nc includes two stackable secondary actuating assemblies 27, disposed between the first and second caps 22nc, 24nc. Each stackable assembly includes an actuating cartridge 26nc, an intermediate deformable diaphragm 37, first and second intermediate chambers 48nc, 50nc, an intermediate piston 41nc, and static sealing elements 38a, 38b, 38c and 38d. Of course, it is possible to insert a different number of stackable assemblies 27 between the top and bottoms caps, according to the weight-force one wishes to apply on the actuating stem 42.

With reference to FIGS. 6, 9 and 10, the components of one of the two stackable assemblies will be described in more details. The other assembly has an identical configuration and comprising the same components. The actuating cartridge 26a-nc is provided with a cartridge channel 260a (identified in FIG. 10), for allowing pressurized fluid injected in the actuator to pass through it. The cartridge is to be used in combination with an intermediate deformable diaphragm 37a, having first and second surfaces 370a, 372a.

When in use, such as in FIG. 6, the stackable assembly 27a comprises a first intermediate chamber 48a-nc, which is limited by the first surface 370a of the intermediate diaphragm 37a. This first intermediate chamber 48a-nc is airtight and in fluid communication with inlet 28. As such, the cartridge inlet 29a is in fluid communication with the main inlet 28. Alternatively, it can also be considered to provide the first intermediate chamber with its own intermediate cartridge inlet, for example provided in the sidewall of the actuating cartridge. The assembly 27a also includes a second intermediate chamber 50a-nc, limited by the second surface 372a of the intermediate diaphragm 37a. The second intermediate chamber 50a-nc is in fluid communication with a cartridge outlet 31a, for expelling the fluid contained in the second chamber.

Still referring to FIGS. 6, 9 and 10, the assembly 27a includes an intermediate piston 41a, which is movable between the actuated and unactuated positions. The intermediate piston 41a includes a piston surface, which is part of a 410a which extends in the second chamber 50a-nc. The piston surface is operatively attached to a surface of the diaphragm, towards the center of the diaphragm. The intermediate piston 41a fits in the cartridge channel 260a, and operatively cooperates with the main piston 34nc. By "operatively cooperating", it is meant that the intermediate piston 41a is linked, either directly or indirectly, to the main piston 34nc. In the present case, the intermediate piston 41a is provided with an axial channel 414a extending through it. This channel 414a is in fluid communication with the main inlet 28 and with the first intermediate chamber 48a-nc. The intermediate piston 41a is linked to the main piston 34nc via the screw 56a. The intermediate piston 41a is connected to the screw 56a which also has an axial channel extending through it. This axial channel of screw 56a is aligned with channel 414a of the intermediate piston 41a. The screw 56a allows to sealingly compress the second intermediate diaphragm 53a around its central hole, with the cartridge 26a. The head of screw 56a is in contact with the main piston 34nc, and is advantageously provided with a cross-shape groove, for facilitating the passage of the pressurized fluid in the first chamber 48nc. As it can be appreciated, the axial channel of the top cap 22nc, and the other screws 56 of the actuator are also provided with such cross-shape groove, for allowing the fluid to flow in the corresponding chambers.

Referring to FIGS. 6, when pressurized fluid is flown through the main inlet 28 and cartridge inlets 29a, 29b, the first intermediate chamber expands, deforming the intermediate diaphragm 37a and moving the intermediate piston 41a from the unactuated to the actuated position, the piston 41a sliding upwardly within the cartridge channel 260a, and assisting the compression of the biasing mechanism 32.

Still referring to FIG. 6, and also to FIG. 10, the intermediate diaphragm 37a is circular and provided with a central hole 374a. Also, the intermediate piston 41a has a first portion 412a extending in the first intermediate chamber 48a-nc, and has a diaphragm retaining nut 60a screwed onto it, for sealingly compressing the intermediate diaphragm 37a around the periphery of its central hole 370a, between nut 60a and the flange section 410a. The intermediate diaphragm 37a is also sealingly compressed along its outer periphery between the cartridge 26a and cartridge 26b of the lower stackable assembly with static sealing element 38b. Of course, in the case of assembly 27b, the outer periphery of intermediate diaphragm 37a is compressed between cartridge 26b and the bottom cap 24nc.

11

The cartridge **26a-nc** is provided with threads **264** provided on its lateral wall, for engaging with adjacent caps and/or cartridges **26nc**.

As shown in FIG. 6, the first intermediate chamber **48a-nc** is limited by the second intermediate deformable diaphragm **53b**. This second intermediate diaphragm **53b** delimits said first intermediate chamber **48a-nc** from an adjacent one of the chambers, and it allows movement of the intermediate piston **41a** while keeping the first intermediate chamber **48a-nc** airtight. Similarly, the second intermediate chamber **50a-nc** is delimited by the second intermediate diaphragm **53a**.

Referring to FIGS. 4-10, the diaphragms **36**, **37**, **52**, **53** are each preferably made of a thin disc-shaped sheet having ripples to allow circulation of the actuating gas, but more importantly to provide it with adequate properties with regards to flexibility and deformability. The diaphragm can be made from polymer, elastomer, rubber, or metal, or from a combination of these elements. It can be filled or not. As explained earlier, bellow(s) can be used as diaphragm(s). In the case illustrated, each of the diaphragms is provided with a hole in its center, for receiving one of the pistons **34**, **37** or of the screws **56**. The respective inner rims of the diaphragms are affixed or snapped between the pistons **34**, **41** and screws **56** and/or nuts **54**, **60**.

Metal gaskets **38** allows better sealing and avoids rotational force of the nuts **54**, **60** to be transferred to the diaphragms **36**, **37**, **52**, **53**.

Still referring to FIGS. 4-10, the top cap **22nc**, the bottom cap **24nc** and each of the actuating cartridges **26a**, **26b** have a cylindrical shape and are each provided with a circular side wall. The sidewalls are respectively provided with threads for engaging with threads of the sidewall of an adjacent one of the bottom cap, top cap and actuating cartridge. Of course, it can also be considered to braze adjacent cartridges instead.

The two actuating cartridges **26a**, **26b** each has a radial wall delimiting first and second sections. As shown in FIG. 10, for cartridge **26a-nc**, the radial wall **262a** is provided with the axial channel **260a**. Cartridge **26b-nc** has an identical configuration. For each cartridge **26**, the side walls of either one of the bottom section and top section includes one outlet, for example a vent, for expelling fluid.

Still referring to FIG. 6, at the bottom portion of the actuator **200nc**, the cap channel **240** receives the screw **57** and a diaphragm **52b** maintained in place with a connecting and closing nut **64**. The screw **57** is connected to the actuating stem **42**, which is connectable to a plunger or to an auxiliary valve mechanism which is to be moved up and down by the actuator. The bottom cap **24** has a narrower portion provided with internal threads **62** designed for allowing a connection to another system, for example a diaphragm valve used in atomic layer deposition.

FIGS. 7 and 8 are respectively top and bottom perspective views of the cross-section of FIG. 6. They allow to better visualize the connections between the different elements of the actuating mechanism **200nc** and how the diaphragms **36** defines first and second chambers **48nc**, **50nc**. As best seen in FIG. 7, the second chamber **50nc** as an initial volume which is decreased when actuating fluid is injected in this normally closed mechanism **200nc**, as it will be explained later. This second chamber **50nc** is defined by the top surface **362** of the diaphragm **36**, the inner surface of the top cap **22nc**, the outside surfaces of the piston **34** and nut **54**, and the bottom surface of the second diaphragm **52**.

The first chamber **48nc** is best seen in FIG. 8. This first chamber **48nc** is defined by the bottom surface **360** of the

12

diaphragm **36**, the inner walls of the cartridge **26a**, the lateral surface of the nut **60**, and the top surface of the second diaphragm **53a**. This chamber **48** will increase in volume when actuating gas is injected in the actuating mechanism **200nc**. When several actuating cartridges **26** are used, first chambers of each cartridge communicate with each other through a fluid communication channel **70** passing along the central axis of the actuator.

Operation of the actuating mechanism **200nc** will be explained with reference to FIG. 11. Pressurized fluid is injected within the actuator through the main inlet **28** of the top cap **22nc**, and follows the path indicated by arrow **72**. Because there is a small gap between the head of screw **56** and the inlet **28**, some of the pressurized gas flows above the top surface of the diaphragm **52a**. Most of the pressurized gas will be flown within the axial channel **66** of the screw **56**, and then within the channel **66** of the main piston **34**. The connection between the screw **56** and the upper portion of the piston **34** being airtight, the pressurized gas will be forced to exit at the opening located in the first portion of the piston **34** in the interstice defined between the lower most surface of the piston **34** and the upper most surface of the screw **56a**.

Thanks to the cross-shaped groove made at the upper surface of the screw **56a**, the pressurized gas will be directed towards the first chamber **48nc**. This first chamber **48nc** being airtight, thanks to the gasket **38b** located between the top cap **22nc** and the cartridge **26a**, pressurized gas will inflate the first chamber **48nc**, forcing the diaphragm **36** to deform, which in turn will push against the bottom face of the piston **34**. The piston **34** will then move upwardly and its top face, in contact with the biasing element **32**, will compress it from an extended to a compressed position. As several actuating cartridges **26** are used, the pressurized gas will continue its course throughout axial channels **66** of screw **56a** and intermediate pistons **41a**, and **41b**, filling in subsequent first chambers **48a-nc**, and **48b-nc**.

Just as described above, the pressurized gas will exit below the bottom surface of the intermediate piston **41a**, right above the top surface of the screw **56b**, and will be forced into the first chamber **48a-nc**, located below diaphragm **37a**. The volume of the first chamber **48a-nc** will increase, deforming the diaphragm **37a**. The volume of the second chamber **50a-nc** will decrease, air exiting through the vent **30a**. The deformation of diaphragm **37a** will cause the intermediate piston **41a** to move upwardly, further assisting the compression on the biasing element **32**. The same phenomenon will also occur in the actuating cartridge **26b**, further increasing the force applied on the biasing element **32**.

Thus, as one can appreciate, the use of several stackable secondary actuating assemblies allows applying a greater weight force on the biasing element **32** while using the same actuating pressure. The screws **56**, **56a**, **56b** and **57**, the piston **34** and the intermediate pistons **41a** and **41b** are all provided with axial bores or channels, which form a communicating channel **72** from the inlet **28** down to the last opening located between intermediate piston **41b** and screw **57**. The screw **57** is not provided with a bore. The lowermost screw **57** being connected to the shaft **42**, the overall upward movement occurring within the actuator **200nc** under the pressurized gas action will cause the shaft **42** to move from its unactuated position (normally closed) to the actuated position, in this case, from a downward to an upward position. The piston **41b** can be connected directly to the screw **57**, for example with threads or by soldering both elements **41b** and **57** to one another, or alternatively a spring

13

can be located below the stem 42, such as shown in FIG. 23B, forcing contact between the piston 41b and the screw 57. The second diaphragms 52a, 52b and 53a, 53b not only help defining the chambers, they also allow the actuating mechanism to move upwardly and downwardly within the actuator 200nc, thanks to their capacity to flex and deform. When the shaft 42 moves upwardly, the outer perimeter of each diaphragm 52a, 52b and 53a, 53b stays put between the connecting nuts and the wall of the caps or cartridges, and it is their portions that move up and down, following the vertical movement of the pistons 34, 41a, 41b. The grooves of the diaphragms facilitate their deformation.

Now with reference to FIG. 12, another version of an actuator of the invention is shown. This version is a normally open actuator 200no, and comprises the top cap 22no, two actuating cartridges 26a-no, 26b-no, and the bottom cap 24no.

With reference to FIGS. 13A and 13B, the different elements or components of this normally open actuator 200no are shown. They are for the most part similar to the ones described for the normally closed mechanism, one of the main differences being that the biasing elements 33 are disposed within the bottom cap 24no rather than within the top cap, and preferably consists of Belleville washers or wave spring rather than one or more compression springs. The piston 34 is also formed integrally with the shaft 42, the biasing action of the wave spring 33 pressing against the flange section 340 of the piston 34 (best shown in FIG. 14), thus maintaining the shaft 42 in a normally open unactuating position.

With reference to FIGS. 14-16, these two cross-section views allow to better visualize the connections between the different components of the actuator 200no, which include a main actuation assembly 25 and two stackable secondary actuating assemblies 27a, 27b. Mainly, the top cap 22no is provided with the inlet 28 for receiving a pressurized actuating gas. This inlet 28 is connected to a central bore, or axial channel 66, provided in the intermediate piston 41a, which is connected to screw 56a, also provided with an axial channel.

Disposed within the top cap 22no and the cartridge 26a is intermediate deformable diaphragm 37a. The intermediate diaphragm 37a is provided with grooves and has a central hole for receiving a first portion 412a of the intermediate piston 41a (identified in FIG. 14). The diaphragm 37a is sandwiched between nut 60a and the flange section 410a of the intermediate piston 41a. The connection is airtight, thanks to a gasket 38c. At the outer periphery of the diaphragm 37a, there is another gasket 38b for providing an airtight connection of the diaphragm 37a with the top cap 22no and the cartridge 26a. This gasket is also an anti-rotational device, which protects the diaphragm against its twisting when it is sandwiched.

Best shown in FIG. 15, the diaphragm 37a, together with the cartridge 26a, defines a second chamber 50a-no which can decrease in volume when pressurized gas is injected within the actuator 200no. Air present within the second chamber 50a-no can exit through the vent 30a when the diaphragm 37a is deformed under the action of the pressurized gas. A first chamber 48a-no is defined between the upper surface of the diaphragm 37a and the inner wall of the top cap 22no. FIG. 16 is another perspective view of the actuator of FIG. 15, which allow to better visualize the interrelation of the different components of actuator 200no. Cartridge 26b-no has a configuration similar to cartridge 26a-no.

14

Back to FIG. 14, a smaller diaphragm 52a is disposed within the first cartridge 26a, and sandwiched between the screw 56a and the lower portion of the intermediate piston 41a, at its center. Its outer periphery is sandwiched between cartridge 26a and nut 54a and the connection is airtight, thanks to the use of a gasket 38a. Similar components and connections are also present in the cartridge 26b-no, with diaphragm 53b for example. The biasing elements 33 are disposed within the circular recess 242 of the lower cap 24no. The biasing elements 33 are embodied, as described earlier, by a wave spring, which presses against the bottom face of the piston 34, forcing the shaft 42 upwardly in the unactuated, biased position (or open position). Just as for the normally closed actuating mechanism 200nc, the normally open mechanism 200no, the bottom cap 24no ends in a narrowing portion and is provided with internal threads 62 allowing the actuator 200no to be connected to another system. The shaft 42 can thus be connected to the plunger of such system, in order to close or open a valve.

FIGS. 17 and 18 show the different components of one of the two stackable secondary actuating assemblies, for the normally open actuator 200no. Both the screw 56a and the intermediate piston 41a are provided with axial channels 66 to allow passage of the actuating gas. The first intermediate chamber 48a-no is limited by the first surface 370a of the intermediate diaphragm 37a. When in use, the first intermediate chamber 48a-no is airtight and in fluid communication with either one of the main inlet 28 of the actuator, provided in the top cap 22no, or with a cartridge inlet. When in use, a second intermediate chamber 50a-no (shown in FIG. 15) is created and limited by the second surface 372a of the intermediate diaphragm 37a. The cartridge 26-no is to be used with second diaphragm 53a, screw 56a, nuts 54a and 60a, intermediate diaphragm 37a and intermediate piston 41a, as well as with gaskets 38b and 38c.

Now with reference to FIG. 19, operation of the normally open actuator 200no will be explained. Pressurized gas is flown into the inlet 28 following the path 72, and gas will flow over the top surface of the first portion 410a of the intermediate plunger 41a towards the first chamber 48a-no, this chamber being airtight, thanks to the gaskets 38c, 38b. The volume of the chamber 48a-no will increase, thereby deforming the diaphragm 37a downwardly, causing in turn a downward movement of the intermediate plunger 41a. Gas contained in the second chamber 50a-no will be pushed outside the actuator 200no, exiting through the vent 30a. Pressurized gas will continue its course through the inner central bore 66 of screw 56a, exiting in the grooves of the head of screw 56a and the upper most surface of the intermediate plunger 41b. Again, pressurized gas will fill the first chamber 48b-no, causing the deformation of the diaphragm 37b, in turn pushing the intermediate plunger 41b downwardly. Air contained in the second chamber 50b-no will be pushed outside through the vent 30b. At the third stage of the actuator 200no, the pressurized gas will through the grooves of the head of screw 56b and upper most surface of the piston 34, filling in the first chamber 48no. The bottom face of the piston 34, in contact with the biasing element 33, will compress the biasing element 33, forcing the shaft 42 downwardly from the unactuated position (normally open) to the actuated position.

Referring now to FIGS. 20 to 22, another embodiment of an actuator of the invention is shown. Most of the components of this actuator 200nc are similar to the ones from actuator 200nc, of FIG. 6. However, in this variant of the actuator, for each of the stackable secondary actuating assemblies, the flange section 4100a of the intermediate

15

piston **410a** and the flange of the main piston **34** have about the same diameter. In other words, intermediate pistons **410** have a larger diameter compared to the version shown in FIG. 6, and their respective diameters substantially correspond to the diameter of the flange section of piston **34**. Providing the flange section of the intermediate piston **410** with a larger diameter allows distributing the pressure applied by the diaphragm **37a** on the intermediate piston **410** when the first chamber is filled with pressurized gas. This embodiment also includes a protection disk **74**, allowing protecting the diaphragm **37a** of the stackable assembly, for example for packaging purposes. Indeed, since cartridges **26** can be packaged and sold separately, protection disks **74** allows protecting the intermediate diaphragms **37** which would otherwise be exposed when not in use. A protection disk can also be provided for the top and/or bottom caps **22**, **24**. When in use in an actuator, the disk **74** limits the first chamber of the corresponding assembly. Of course, the normally open actuator **200no** can also include stackable secondary actuating assemblies in which the flange of the intermediate pistons is larger, similar to the main piston. The stackable assemblies can also include a protection disk, similar to the one shown in FIGS. 19-20.

With reference to FIGS. 23, 23A and 23B, another embodiment of the actuator according to the invention is shown. This actuator **20dv** comprises a single stackable secondary actuating cartridge **26dv**, disposed between the first and second caps **22dv**, **24dv**, and includes a second actuating stem **44** for actuating a second plunger, in addition to actuating stem **42**. In the present case, the main inlet **28dv** is provided in the stackable cartridge, rather than in one of the caps, contrary to other embodiments of the actuators previously described. The first cap **22dv** and second cap **24dv** are provided with respective cap channels **241**, **240** (identified in FIGS. 23A and B). The second actuating stem **44** slidably fits in the second cap channel **241** and a portion of the second stem **44** extends outside the second cap **22dv**. The second actuating stem **44** slides within the cap channel **241** when the main piston **34** moves between actuated and unactuated positions. The second actuating stem **44** can be connected or integrally part of the main piston **34**, as in the present case. It can also be considered to provide a double-stem actuator in which the stems move in opposite directions. In this case a fluid tight plate is placed across the actuator, thus creating a double-actuator.

Referring to FIG. 23B, when actuator **20dv** is unactuated, biasing element **32** presses the main piston **34** and the intermediate piston **410**, maintaining them in their unactuated positions. In the present case, the biasing element **32** pushes the main piston **34** and intermediate piston **410** downwardly, the actuating stem **44** being retracted towards the first cap **22dv**.

For actuating the actuator, pressurized fluid is flown through main inlet **28**, which is in fluid communication with cartridge inlet **29**. The pressurized fluid fills the first chamber **48dv** and the first intermediate chamber **48a-dv**, thereby deforming the diaphragms **36**, **37**, which will in turn move the main piston **34** and intermediate piston **410**. In the present case, the main piston **34** and intermediate piston **410** are move upwardly, compressing the biasing element **32**. Since the main piston **34** moves upwardly, and the second actuating stem **44** is connected to it, the actuating stem **44** will move upwardly as indicated by the uppermost arrow on the right side of the drawing.

By compressing the biasing element **32**, pressure will be removed from the actuating stem **42**, allowing it to move from a lowered to a raised position. Preferably, biasing

16

elements **35**, in this case a wave spring, further assist the actuating stem **42** to move from the actuated to the non-actuated position, and in this case, from a lowered to a raised position, the biasing element **32** having a stronger biasing force than biasing element **35**. As the first chambers **48dv**, **48a-dv** expand, the second chambers **50dv**, **50a-dv** deflate and fluid is expelled from the main outlet **30** and the cartridge outlet **31**.

Of course, it is possible to control movement of the actuating stems **42**, **44** by modifying or adjusting the biasing forces of the respective biasing elements **32**, **35**, and by controlling the pressure of the fluid injected through the main inlet **28dv**.

It can also be considered to retrieve the biasing spring **32** and to replace it with a controllable source of pressurized fluid which would, when the actuator is in the unactuated position, perform the same task as the biasing element **32**, which consists in forcing the main piston **34** in the unactuated position (for example downwardly). When actuated, the controllable source depressurizes the hollow portion of cap **22dv**, creating a vacuum which would accelerate deflation of second chamber **48dv**. Similarly, in order to increase the actuating speed of the actuator, it can be considered to connect the outlet **31** of the stackable secondary actuating cartridges to a vacuum source.

As such, the biasing mechanism of the actuator of the present invention can be a controlled source of pressurized fluid, for biasing the main piston **34** in its unactuated position.

FIGS. 24 and 24A show a double acting actuator, which is especially advantageous in high temperature applications. Indeed, extreme temperatures can render the biasing element ineffective. The double acting actuator uses the actuation pressure to move the shaft upwardly or downwardly. In this variant of the actuator, there are no vents, and the outlets are connected to an actuation line. One actuation line is used to pressure one side of the diaphragms while the other is used to flush back previous actuation gas.

Now referring to FIGS. 24 and 24A, an actuator **20da** is shown in combination with a source of pressurized fluid **80** and with a source of vacuum **82**. In this case, two actuating sources are used, and the vacuum source is used as a biasing mechanism. The source of pressurized fluid **80** is in fluid communication with the main inlet **28** and with the cartridge inlet **29** of the stackable secondary actuating assembly **27**. Similarly, the source of vacuum **82** is in fluid communication with the main outlet **30** and with the cartridge outlet **31**.

Another advantage of this variant of the actuator is that by depressurizing the second chambers **50da** and **50a-da** with a vacuum source **82**, the actuator can be actuated more rapidly, thus increasing the actuating speed of the actuator, or in other words, the response time of the actuator.

Of course, it can also be considered to actuate the actuator by only connecting the outlets **30**, **31** to a vacuum source **82** such as to draw fluid from the second chambers **50da**, **50a-da**, and without forcing fluid in the inlet(s) of the actuator. Depressurizing the second chambers **50da** and **50a-da** of the actuator has the same effect as pressurizing the first chambers **48da**. Of course, both actuation sources can be used simultaneously, by forcing fluid through the main inlet **28** of the actuator and by retrieving fluid from the main outlet **30** and/or cartridge outlets **31**.

As shown in FIG. 24B, it can also be considered to force pressurized fluid through the ports **30**, **31** and/or to draw fluid from the main port **28**, thus inverting the movement of the actuating stem **42** when connected to the source of pressurized fluid. Using a controllable source of pressurized

17

fluid connected to the inlet(s) and/or the outlet(s) of the actuator allows controlling the displacement direction and the speed of the actuating stem 42.

Now referring to FIG. 25, the actuator 20ip is used in combination with a current to pressure converter 84. This source of fluid to the actuator is controlled by a current input signal entering the current to pressure converter 84. As such, the position of the actuating stem 42 can be finely controlled and tuned according to the current signal entering the current to pressure converter. The source can be used to push fluid into one or both inlets of the actuator. Actuator position feedback could also be added to provide a complete valve positioner as commonly used in the industrial and process control field.

The actuator of the present invention can be used as a "spring return fail safe position linear actuator" usable with a current to pressure (I to P) converter, such as shown in FIG. 26. The actuation pressure can be increased (or decreased) gradually, in order to smoothly compress (or depress) the biasing element, allowing a precise modulating of the position of the actuating shaft. When properly calibrated, this variant of the actuator linked with an "I to P" converter becomes a linear actuator.

It can also be considered to provide each of the cartridges with its own cartridge inlet, for increasing the actuating speed and/or reducing the gas at each stage of the actuating mechanism.

With reference to FIG. 26, the actuator 26b includes a stackable secondary cartridge assembly which comprises a cartridge biasing element 39 for biasing the intermediate piston 41 of the corresponding assembly 270, in the unactuated position. Advantageously, the cartridge biasing element allows to further control the weight-force applied on the actuating shaft in its unactuated position.

With reference to FIGS. 27 and 28, two other possible embodiments of an actuator are shown. The embodiments shown are normally-closed actuators. However, these embodiments could use similar components so as to form normally-opened actuators. These embodiments are especially adapted for industrial applications. While these two variants of the actuator are shown with three cartridges and actuating assemblies, it is possible to stack and connect more or less cartridges, depending on the desired torque or weight-force required to actuate a plunger. As can be appreciated, just as for the other embodiments described previously, the actuator of the present invention is modular. This architecture allows building actuators having different forces using the same set of components. Stock-keeping of components can thus be simplified. In addition, the "foot-print" or width/diameter required by actuator remains the same, even if the number of cartridges from one actuator to another varies.

Referring to FIG. 27, the actuator 200' comprises a first or topmost cap 22' and a second or lowermost cap 24'. The first and second caps 22', 24' face one another, even though they are not directly connected. In some embodiments, it is possible to connect the first cap 22' to the second cap 24' directly, so as to form a single cartridge. In the present case, the actuator 200' includes several stackable actuating cartridges 27', with two outermost cartridges and a middle cartridge. The cartridges 27' are bolted together, but other types of connections are possible, such as with screw threads, similar to the other embodiments presented previously. In this particular example, the different cartridges 27' are connected with rods 85' passing through nut-shaped protuberances or eyelets, protruding from the sidewalls 266'

18

of the cartridges 27'. A system of bolts and nuts allows for easy assembly/disassembly of the different cartridges.

The different components of the stackable actuator cartridges will be described with reference to the middle cartridge 27'. Most components of the other two outermost cartridges are similar to those of the middle cartridge. The cartridge 27' includes a first diaphragm 36' and a second diaphragm 52'. The first diaphragm 36' delimits a first chamber 48' from a second chamber 50'. The chambers are further limited by top, bottom and side walls of the cartridge 27'. In this particular example, the cartridge is made of two hollow bodies, 270', and 270'', each including a cartridge channel 272'. The cartridge channels 272' allow for the piston assemblies of each cartridge to cooperate with each other. In this example, the inlet 29' is provided in body 270' while the outlet 31' is provided in body 271', but the inverse is also possible. That said, it is possible for the cartridge to be made of a single body, as shown in previous examples. The first chamber 48' is in fluid communication with the cartridge inlet 29', while the second chamber 50' is in fluid communication with the cartridge outlet 31'. The inlet 29' is typically connected to a source of pressurized fluid, typically compressed air. The outlet 31' can be used as a vent, or be connected to a vacuum source for example.

Different materials can be used of the diaphragms, with varying degrees of stiffness, depending on the application in which the actuator is used.

The second diaphragm 52' delimits the first chamber 48' from adjacent chambers of adjacent cartridges. The first diaphragm 36' typically extends from the center of the cartridge to the sidewalls of the cartridge, while the second diaphragm 52' is smaller, and is sized and configured to fit with the channels 272'.

The cartridge 27' is provided with a piston assembly 34', movable between actuated and unactuated positions. The piston assembly 34' includes a flange portion 340' extending in one of the chambers, in this case the first chamber 48'. The flange portion 340' preferably extends along the first diaphragm 34, and is in contact with a flat portion of the diaphragm 34, so as to spread and transmit the force of the pressurized fluid substantially evenly on the surface of the diaphragm. The piston assembly 34' also has a first or head portion 342' passing through the first diaphragm 36, extending in the second chamber 50. The flange and head portions 340', 342' can be integrally formed as a single component, or consist of two different components. The piston assembly 34' also has a second or base portion 344', opposite the head portion 342'. The piston assembly 34' is sealingly affixed to the first diaphragm 34' via the flange and the head portions 340', 342'. The base portion 56' cooperates with the head portion of the piston assembly located underneath, and the head portion 342' cooperates with the base portion of the top, adjacent cartridge.

Of course, in the case of the two outermost cartridges, the head and base portions cooperate with other types of components. For the topmost cartridge, the head portion cooperates with the spring 32', via a transfer plate, and for the lowermost cartridge, the base portion cooperates with the plunger (not shown) to actuate, via the stem 42'. For normally-open actuators, this configuration can be inverted, as shown in previous embodiments. The actuating stem 42' extends through a cap channel 240 provided in the second cap 24'. The actuating stem 42' is connectable to a plunger and cooperates with the piston assemblies 34' to slide within the cap channel 240 and move between actuated and unactuated positions.

19

When pressurized fluid is forced through or drawn from the cartridge inlets 27', the first chambers 48' of the stackable actuating cartridges expand, moving the piston assemblies from the unactuated to the actuated position, and thereby moving the actuating stem 42'. In the embodiment of FIG. 27, the actuator 200' includes a continuous path 72' for the pressurized fluid, which extends axially from the first to the second caps, and through each of the stackable actuating cartridges 27'. While in previous embodiments the fluid path extended centrally in the actuator, through the piston assemblies, in this particular example the fluid path extends laterally relative to the piston assemblies, and is provided in the sidewalls of the cartridges 27'. The path 72' is connecting to the cartridge inlets 31'. Each cartridge 27' comprises an axial channel 66', the channels 66' being aligned and forming part of the continuous path 72'.

Referring to FIG. 28, the actuator 200" shown is similar to the one of FIG. 27, but for the continuous path. Each cartridge inlets 29' is independent from the other inlets, and the first and/or second chambers of the cartridges are fluidly isolated from each other. This embodiment is advantageous as it allows actuating the cartridges individually. For example, it can be decided to only actuate the lowermost cartridge provided with the actuated stem, while not actuating the other cartridges. The same actuator architecture can thus be used to provide different actuating forces.

Back to FIG. 27, the piston assembly 34' of the stackable cartridge 27' is affixed to both the first and the second diaphragms 36', 52', and is maintained when the cartridge is removed from the actuator. In this embodiment shown, but also as shown in some of the previous embodiments, the piston assembly 34' is fixedly connected or affixed to both the first and second diaphragms via screwed components. This allows for the stackable actuating cartridges to be modular. This type of connection also allows for easier replacement of damaged parts/components of the actuator. In the embodiment of FIG. 27, the first chamber 48 remains formed between the two diaphragms, even during disassembly of the actuator. The head portion 342' of the piston assembly 34' is preferably fixedly connected to the first diaphragm 36', while the base portion 344' is fixedly connected to the second diaphragm 52'.

The piston assembly 34' is preferably provided with a screw or nut 60' screwed to the head of the piston, fixing the head portion of the piston to the first diaphragm 36. Still preferably, a second screw and/or nut 56' is screwed to the base portion 344' to fix it to the second diaphragm 52'.

The first and second diaphragms 36' 52' comprise respective inner and outer peripheries. For each diaphragm, the inner periphery defines a central hole in the diaphragm, as is typical. In order to improve sealing of the cartridges to one another, the actuating cartridges comprise static seals provided at the inner and outer peripheries of the first and second diaphragms. This provides static sealed connections between the head portion 342' of the piston assemblies 34' and the first diaphragms 36', and between the base portion 344' of the piston assemblies 34' and the second diaphragms 52', respectively. Advantageously, the seals are squeezed between the different connected components, limiting potential wear resulting from friction of the seals against moving parts.

As it can be appreciated, the actuating mechanism of the present invention eliminates friction of sealing element against inner wall of cartridges, and reduces the number of moving parts, and is therefore particularly advantageous in high or low temperature applications. The sealing elements in the present actuating mechanism are static, and it is the

20

movement or deformation of the diaphragm that initiates movement of the piston(s) and of the actuating stem or shaft.

In addition, having stackable actuating cartridges allow increasing the torque or weight-force applied to the actuating stem(s), using the same actuating pressure for the fluid. The actuator of the invention can be customized according to different types of applications, by adding or removing stackable secondary actuating cartridges and/or cartridge biasing elements.

Advantageously, the same components of the actuator can be used for a large variety of applications, limiting the number of different parts to manufacture and keep in stock. Another advantage of the invention is that it facilitates the maintenance of the actuator, the same parts being used from one actuating cartridge to another. Yet another advantage is the increase of useful life of the mechanism in addition to the increase of the time intervals between maintenance activities, since the friction between moving parts is reduced, if not eliminated, thanks to the static sealing elements.

The present invention also concerns a kit for mounting the actuator as described above. The kit includes at least a top cap and a bottom cap, a main actuation assembly which includes the deformable diaphragm and the main piston, an actuating stem or shaft, and a biasing element. The kit can also include the different connecting and sealing components, such as the nuts, screws and gaskets described above.

Of course, numerous modifications could be made to the embodiments described above without departing from the scope of the present invention.

The invention claimed is:

1. An actuator for actuating a plunger, the actuator comprising:

first and second caps facing one another, the second cap being provided with a cap channel;

a plurality of stackable actuating cartridges provided between the first and second caps, each of said stackable actuating cartridges comprising:

a cartridge inlet and a cartridge outlet;

first and second diaphragms;

the first diaphragm delimiting first and second chambers, the first chamber being in fluid communication with the cartridge inlet, the second chamber being in fluid communication with the cartridge outlet;

the second diaphragm delimiting one of the first and second chamber from an adjacent chamber;

a piston assembly movable between actuated and unactuated positions, the piston assembly comprising a flange portion extending in one of the first and second chambers, a head portion passing through the first diaphragm and extending the other one of said first and second chambers and a base portion, the piston assembly being sealingly affixed to the first diaphragm via the flange and head portions, the head portion of the piston assembly cooperating with the base portion of a piston assembly part of an adjacent stackable actuating cartridge;

an actuating stem provided in said cap channel, a portion of the stem being connectable to the plunger, the actuating stem cooperating with the piston assemblies of the stackable actuating cartridges to slide within the cap channel when piston assemblies move between the actuated and unactuated positions; and

a spring biasing the piston assemblies in the unactuated position;

wherein when pressurized fluid is forced through the cartridge inlets or drawn from the cartridge outlets, the

21

first chambers of the stackable actuating cartridges expand, moving the piston assemblies from the unactuated position to the actuated position, the actuating stem thereby sliding within the cap channel.

2. The actuator according to claim 1, wherein the piston assembly of each of the stackable actuating cartridges is affixed to both the first and second diaphragms, such that connection of the piston assembly with the first and second diaphragms is maintained when a given one of the stackable actuating cartridges is removed from the actuator.

3. The actuator according to claim 1, wherein the piston assembly is fixedly connected to both the first and second diaphragms via screwed components.

4. The actuator according to claim 3, wherein the head portion of the piston assembly is fixedly connected to the first diaphragm and the base portion of the piston assembly is fixedly connected to the second diaphragm.

5. The actuator according to claim 3, wherein the piston assembly is provided with a first screw or nut screwed to the head portion of the piston, fixing the head portion of the piston to the first diaphragm between said screw or nut and said flange portion.

6. The actuator according to claim 5, wherein the piston assembly is provided with a second screw or nut screwed to the base portion of the piston, fixing the base portion of the piston to the second diaphragm.

7. The actuator according to claim 3, wherein the first and second diaphragms each comprises inner and outer peripheries, the inner periphery defining a central hole, each of said stackable actuating cartridges comprises static seals provided at the inner and outer peripheries of the first and second diaphragms, providing static sealed connections between the head portion of the piston assembly and the first diaphragm, and between the base portion of the piston assembly and the second diaphragm, respectively.

22

8. The actuator according to claim 3, comprising a continuous path of extending from the first to the second caps, and through each of the plurality of stackable actuating cartridges, for circulating the pressurized fluid.

9. The actuator according to claim 8, wherein the stackable actuating cartridges comprise respective axial channels, said axial channels being aligned and forming part of the continuous path.

10. The actuator according to claim 9, wherein the axial channel passes through the piston and through the first and second screws or nuts.

11. The actuator according to claim 8, wherein the continuous path extends laterally relative to the piston assemblies, in sidewalls of the stackable actuating cartridges.

12. The actuator according to claim 8, comprising a main inlet provided in the first cap, the main inlet being in fluid communication with each of the cartridge inlets of the plurality of stackable actuating cartridges.

13. The actuator according to claim 1, wherein each of the cartridge inlets are independent from one another, with the first chambers of each of the stackable actuating cartridges being fluidly isolated from one another.

14. The actuator according to claim 1, wherein at least some of said stackable actuating cartridges comprises first and second hollow bodies further delimiting the first and second chambers.

15. The actuator according to claim 1, wherein the stackable actuating cartridges are removably screwed to one another.

16. The actuator according to claim 1, wherein the stackable actuating cartridges are removably bolted to one another.
